INTRODUCTION

HIV-1 is the most common type of Human Immunodeficiency Virus. It attacks your body's immune system. The virus destroys CD4 cells. These cells help your body fight infections. **HIV-1** can severely damage your immune system and lead to Acquired Immune Deficiency Syndrome (**AIDS**). There is currently no effective cure. Once people get HIV, they have it for life. But with proper medical care, HIV can be controlled. People with HIV who get effective HIV treatment can live long, healthy lives and protect their partners.

Where did HIV come from?

HIV infection in humans came from a type of chimpanzee in central Africa. The chimpanzee version of this virus was probably passed to humans when they came in contact with their infected blood.

Types and Strains of HIV

There are two main types of human immunodeficiency virus - HIV-1 and HIV-2. Both can lead to AIDS. However, they're very different from each other.

HIV-1 is the most common type. When you hear the term "HIV," it's probably HIV-1. HIV-2 occurs in a much smaller number of people, mostly in West Africa.

HIV constantly makes copies of itself. Some strains multiply faster and can be passed from person to person more easily than others.

Your doctor can treat your HIV better if they know what strain you have. A **blood** test can tell you. The same test also can tell if certain HIV drugs won't work well for you.

EXPERIMENTALS

In order to understand the complete organization of Human Immunodeficiency Virus-1, 3-dimensional structure of its was performed using Computational Biology tool. Structure of HIV-1 was downloaded from the Protein Data Bank (PDB ID: 4RVI). The analysis include evaluation of hydrogen bonds and secondary structure using PyMOL software.

RESULTS & DISCUSSION

The structure of GRL0519 (PDB ID:4RVI) contains 2 alpha-helices and 2 beta-helices. Followed by the hydrogen bonds which are 26 in number and the average of the bond length of the 22 hydrogen bonds is 2.87Å.

As the hydrogen bond length is less than 3Å, so they are said to be strong. Each end of the hydrogen bond should be attached to the drug molecule at one end and the other to the water molecule or protein as well which is the primary requirement.

So in this GRL-0519 Protease, there are 7 H-bonds associated with drug and water molecule and 15 H-bonds associated with drug and protein molecule.

Summary of the global HIV epidemic (2019)

	People living with HIV in 2019	People newly infected with HIV in 2019	HIV-related deaths in 2019
Global	38.0 million [31.6 million – 44.5 million]	1.7 million [1.2 million – 2.2 million]	690 000 [500 000 – 970 000 million]
Sub-Saharan Africa	36.2 million [30.2 million – 42.5 million]	1.5 million [1.1 million – 2.0 million]	600 000 [430 000 – 840 000]
Eastern Europe and Central Asia	19.2 million [16.4 million – 22.2 million]	790 000 [580 000 – 1.1 million]	300 000 [220 000 – 420 000]
Latin America and the Caribbean	17.0 million [13.5 million – 20.4 million]	670 000 [430 000 – 1.2 million]	380 000 [280 000 – 560 000]
South and Southeast Asia	1.8 million [1.3 million – 2.2 million]	150 000 [94 000 – 240 000]	65 000 [61 000 – 150 000]
